I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

1

### Production of a Fermentation Product

The present invention relates to processes of treating plant derived material to provide an aqueous liquor containing sugars which are used in a fermentation process to produce a fermentation product. In particular the present invention relates to a process of dewatering a fermentation broth residue, produced as a by-product from the distillation recovery of a fermentation product. Typically the dewatered solids are dried and used as a solid fuel. The clarified water would normally be returned to watercourses and/or used as wash liquor further back in the process.

Typically such fermentation products include for instance ethanol, glycerol, acetone, n-butanol, butanediol, isopropanol, butyric acid, methane, citric acid, fumaric acid, lactic acid, propionic acid, succinic acid, itaconic acid, acetic acid, acetaldehyde and 3-hydroxypropionic acid.

It is known to treat a biomass with acid in order to hydrolyse polysaccharides to the component sugars that can be used in a fermentation process to produce a fermentation product. For instance US-A-4384897 describes a method of treating biomass material in which it is subjected to a two stage hydrolysis in which polysaccharides that are more easily hydrolysed, such as hemicellulose and then in a second stage the more difficultly depolymerisable material e.g. cellulose, is depolymerised using a more severe hydrolytic treatment. The products of the first and second stages include sugar solutions and organic acids, aldehydes. The monosaccharides are subjected to fermentation to produce ethanol and the beer resulting from the fermentation may then be subjected to rectification to produce ethanol of commercial grade. US-A-4384897 sets out to provide improvements in more efficient washing of solids, the use of co-current washing or countercurrent washing of solids and proposes the use of ferric and or aluminium ions as flocculating agents to separate finely dispersed solids resulting from the neutralisation of the hydrolysate liquor stream.

It is also known from an NREL report entitled "Lignocellulose Biomass to Ethanol Process Design and Economics of Co-Current Dilute Acid Prehydrolysis and Enzymatic Hydrolysis Current and Future Scenarios", NREL/IP-580-26167 (July 1999) to treat cellulose as the second polysaccharide by a cellulase enzyme in order to hydrolyse the cellulose into its component sugars. In one form of this process the solid by-product residue resulting from the first hydrolysis step and containing cellulose is divided into a main stream and a secondary stream. The main stream is fed directly into the fermentation vessel and the secondary stream is passed to a cellulase production stage, in which fungi are allowed to grow and act upon the cellulose, such that sugars and cellulase are formed. The sugars and cellulase are then fed into the fermentation vessel and the cellulase acts upon the cellulose from the main stream and converts it into the component sugars which in turn can be fermented to produce the fermentation product.

The treatment of shredded cellulosic material using concentrated acid to provide aqueous solutions of sugars, which can be used in a fermentation process. For instance US-A-4650689 discloses a process of preparing ethanol from cellulosic material by subjecting the cellulosic material to highly concentrated mineral acid gas such as HCl under pressure, and treatment with hot water to give a liquor containing sugars which can be fermented.

US-A-5975439 describes an automated process for producing ethanol by shredding the cellulosic component of municipal solid waste and mixing this with equal amounts of concentrated sulphuric acid at high temperature to provide a digested mixture. The aqueous sugar solution is separated from the solids by a filtration process before being subjected to a fermentation process.

New processes of producing fermentation products are disclosed in patent applications filed in the name of Ciba Specialty Chemicals Water Treatments Limited (references GT/3-.....) filed with equal date to the present application.

However, in the recovery of the fermentation product from the fermentation broth it

is sometimes necessary to continually distill off the fermentation product in a distillation stage, wherein a stillage stream, comprising residues and by-products is removed.

WO-A-8603514 describes manufacture of ethanol by fermentation and then extraction of the ethanol from the fermentation broth. The residual fermentation broth liquor contains yeast and dissolved polymeric materials such as polysaccharides and proteins. An advantage of locating the solid liquid separation stage after the distillation stage is that some part of the non-separable dissolved protein in the fermentation liquor is transferred into a separable form through coagulation due to heating in the distillation and heat exchange processes.

In a study by Ann C Wilkie et al (Biomass and Bioenergy 19 (2000) 63-102, the treatment of ethanol stillage is evaluated. Bacterium, *Zymomonas mobilis* has been shown to produce higher ethanol yields but that there is difficulty in separating the stillage liquor from the solid material. The study also identifies the difficulty in separating suspended solids in sugar crops and cellulosic crops.

In general, the stillage stream or still bottoms resulting from the distillation processes are subjected to solids liquid separation step to produce a dewatered product which can be dried to produce a dry solid fuel product. The aqueous liquid separated from the solids are either returned to watercourses and/or recycled as wash water used in the washing of acid treated plant derived material. The stillage stream or still bottoms normally are high in BOD (Biological Oxygen Demand) and so it is important to ensure that the aqueous liquor is effectively clarified and the water produced therefrom is substantially free of impurities in order not to poison watercourses and/or when used as wash liquor contaminate the substrate that is being washed.

The stillage stream containing precipitated protein based impurities and high levels of lignin, which make it difficult to flocculate and effect solids liquid separation. It is known from an NREL report entitled "Liquid/Solid Separation" 99-

10600/14 (March 2001) to treat post distillate slurry with a single polymer solution of concentration 0.01 to 0.02 wt%, identified as Perc-765, at doses in the range of 0.4 to 1 Kg/tonne of dry solids to effect the dewatering of the solids on a belt press to a final solids content of 26-29 wt%. However, the filtrate clarity is poor, with separation of a dilute feed of concentration 3 to 4 wt% producing a filtrate containing solids of 0.25 wt% or greater. It is noted that when operating with a desired feed concentration of 11.7 wt%, the ability to flocculate the solids may be impacted by this difference and either dilution of the feed, greater mixing intensity, and/or increased polymer dosages may result. Based on the final solids content and the filtrate solids content, belt presses were not recommended for this application. Furthermore, the liquor is normally at an elevated temperature, for instance above 50°C and can be as high as 95°C or 100°C. At these elevated temperatures it is normally even harder to adequately flocculate these liquors. It is therefore an objective to improve the solids liquid separation.

A process of separating suspended solids from a fermentation liquor by subjecting the liquor to solids liquid separation stage, wherein the fermentation liquor is produced in a fermentation process for the production of a fermentation product, which liquor comprises water, lignin and BOD, wherein the solids liquid separation stage is assisted by a treatment system, characterised in that the treatment system comprises either,

- (i) a cationic polymer having an intrinsic viscosity (IV) of at least 4 dl/g at a dose of above 2 kg/tonne based on dry weight of suspension, or
- (ii) a cationic polymer having an intrinsic viscosity (IV) of at least 4 dl/g and,
- (iii) an anionic polymer having, and/or
- (iv) a cationic polymer of intrinsic viscosity of below 4 dl/g and a cationic charge density of at least 3 meq/g and/or
- (v) inorganic coagulants and/or
- (vi) charged microparticulate material.

Intrinsic viscosity is measured using a suspended level viscometer in 1M NaCl buffered to pH 7.5 at 25°C.

We have found that surprisingly the yield and/or efficiency of the process can be improved by effecting a rapid but efficient solids liquid separation of the solid residues from an aqueous liquor containing BOD and that the liquor can be recycled to the fermentation process. The treatment system of the present invention allows a significantly improved separation of liquors from the solid residues and by-products. In particular the process induces more effective flocculation and the separation process is found to be significantly faster. In addition the solid residues, which contain mainly lignin, resulting from the separation process have higher cake solids than conventional separation treatment. Such a solid product would take less time and energy to dry and thus can be for instance used more efficiently as a solid fuel.

Usually the biomass residue comprises in addition to lignin, microbes and residual unconverted cellulose and hemicellulose. Frequently the aqueous liquors will also comprise proteins, polysaccharides, organic and inorganic salts.

It is also important to ensure that very effective separation of liquor from the solid by-product is also achieved more rapidly than conventional treatments.

In one aspect of the present invention the fermentation liquor is subjected to a distillation stage in which the fermentation product is recovered, wherein the liquor is removed from the distillation stage as a stillage stream and then subjected to the solids liquid separation stage. Thus in this form of the invention the fermentation liquor is essentially free of the fermentation product when it is subjected to the solids liquid separation stage.

Alternatively the fermentation liquor contains the fermentation product wherein the liquor is subjected to the solids liquid separation stage and then passed to a distillation stage wherein the fermentation product is recovered. Thus in this form of the invention the solids are removed prior to the distillation stage and thus the distillation column and the stillage stream produced therefrom will be substantially

free of the solids.

We have found that the separation process is particularly effective when the treatment system comprises a second component in addition to the cationic coagulant. In particular a preferred embodiment employs a treatment system which comprises (i) the cationic coagulant and (ii) a high IV cationic polymer of intrinsic viscosity of at least 4 dl/g.

In a treatment system comprising cationic coagulant and high IV polymer, the components may be added simultaneously, either as a pre-mix or alternatively separately. In one preferred form of the invention the coagulant is added first followed by the addition of high IV polymer. The reverse order of addition is also possible and may be particularly suited to certain cases.

The cationic coagulant may be a low IV natural or synthetic cationic polymers which exhibit intrinsic viscosity of below 4 dl/g and a cationic charge density of at least 3 meq/g.

Preferably the low IV is selected from the group consisting of polyamines, amine/epihalohydrin addition polymers, polymers of dicyandiamide with formaldehyde, polymers of diallyldimethyl ammonium chloride (DADMAC), cationic starch and cationic inulin. Polyamines may be commercially available polyamines, for instance polyethyleneimine (PEI). Cationic starch or cationic inulin may be commercially available products.

Preferred coagulant polymers are addition polymers of formaldehyde with dimethylamine and optionally other amines such as ethylenediamine, for example commercially available as Magnafloc<sup>TM</sup> 1597 or polymers of formaldehyde with dicyandiamide, for example commercially available as Magnafloc<sup>TM</sup> 1797. More preferred low IV polymeric coagulants include polymers of water soluble ethylenically unsaturated cationic monomer or blend of monomers at least one cationic, non-ionic or and/or anionic monomer(s) alone or with other water soluble monomers, provided that the polymer has a cationicity of at least 3 meq/g. By

water soluble we mean that the monomer has a solubility of at least 5g/100 ml at 25°C. Particularly preferred polymers are homopolymers of diallyldimethyl ammonium chloride or copolymers of diallyldimethylammonium chloride with up to 20 mole% acrylamide. Typically such polymers would have molecular weights of up to 2,000,000 and usually below 1,000,000. Useful polymers would ideally exhibit an intrinsic viscosity of below 4 dl/g.

Inorganic coagulants may be any suitable inorganic coagulants, for instance alum or polyaluminium chloride (PAC).

When the process also involves a cationic coagulant and a high IV cationic polymer, the high IV polymer may be desirably selected from water soluble or water swellable polymers. The polymer may be a natural polymer or a synthetic polymer which has been formed from ethylenically unsaturated water-soluble monomer or monomer blend. Suitably the high IV polymer is a flocculating agent selected from the group consisting of water soluble or water swellable natural, semi-natural and synthetic polymers. Natural polymers are desirably chitosan. Preferably the polymer is synthetic and may be formed by polymerisation of at least one cationic, non-ionic or and/or anionic monomer(s) alone or with other water-soluble monomers.

Preferably high IV polymeric flocculating agents are formed from ethylenically unsaturated water soluble monomers that readily polymerise to produce high molecular weight polymers. Particularly preferred polymers include monomers that are selected from the group consisting of polyacrylamide, copolymers of acrylamide with (meth) acrylic acid or salts thereof, copolymers of acrylamide with dialkylaminoalkyl (meth) acrylate or acid addition or quaternary ammonium salts, polymers of diallyldimethyl ammonium chloride. The polymers may be linear in that they have been prepared substantially in the absence of branching or cross-linking agent. Alternatively the polymers can be branched or cross-linked, for example as in EP-A-202780.

Desirably the coagulant and high IV polymer are added sequentially, preferably employing the coagulant first. In this way the addition of the coagulant coagulates the suspended solids and the coagulated solids are then flocculated by the bridging flocculant. However, in some instances it may be desirable to add the high IV flocculant first followed by the coagulant. It may also be desirable the coagulant and high IV polymer are added simultaneously, preferably as a premix.

In the case where the treatment system employs a premix, the coagulant may be an inorganic coagulant or the aforementioned low IV polymer. Preferably the premix comprises (i) a low IV cationic polymer of intrinsic viscosity of below 4 dl/g and a cationic charge density of at least 3 meq/g and (ii) a high IV cationic polymer of intrinsic viscosity of at least 4 dl/g.

The coagulant introduced is suitably introduced into the aqueous suspension is any suitable amount in order to effect coagulation of the suspended solids.

Usually the dose of coagulant is at least 50 grams per tonne (based on dry weight of biomass residue). The dose of coagulant is usually significantly higher, but is typically up to 15000 grams per tonne. Usually to amount of coagulant is added in an amount between 500 and 3000 grams per tonne, especially around 750 to 2000 grams per tonne.

When the treatment employs a high IV flocculant with the cationic coagulant, the dosed of flocculant is typically is at least 50 grams per tonne (based on dry weight of biomass residue). The dose of flocculant is usually significantly higher, but is typically up to 15000 grams per tonne. Usually to amount of flocculant is added in an amount between 500 and 3000 grams per tonne, especially around 750 to 2000 grams per tonne.

In order to ensure that the coagulated and or flocculated solids are separated from the liquid medium, the biomass residue is subjected to a mechanical dewatering stage during or subsequent to application of the treatment system. The mechanical dewatering step is ideally selected from at least one of, a centrifuge, a screw press, a filter press, a belt filter press a horizontal belt filter or preferably a

pressure filter.

The liquor separated from the biomass residue comprise sugars and/or cellulose are generally free of unwanted suspended solids and desirably are recycled into a fermentation process in order to produce a fermentation product.

The dewatered biomass residue comprises lignin and thus is generally difficult to dewater. Generally the dewatered biomass residue is subjected to a drying stage and the dried residue may be for instance used as a solid fuel a nutrient source for further fermentation or a source of chemicals. The process enables the manufacture of the fermentation product to be made more efficiently. Preferably the fermentation product is selected from the group consisting of ethanol, glycerol, acetone, n-butanol, butanediol, isopropanol, butyric acid, methane, citric Acid, fumaric acid, lactic acid, propionic acid, succinic acid, itaconic acid, acetic acid and acetaldehyde.

The following example illustrates the invention.

#### Example

**Pre-hydrolysis:** Milled wood chips steamed with low pressure steam to approximately 100°C. After steaming concentrated sulphuric acid is diluted and added to the mixture until the mixture contains 0.52% acid and the solids in the reactor are 22% by weight. The mixture is then steamed heated to 175°C for 15 minutes. The mixture is then flash cooled for 15 minutes to remove 6.5% of the acetic acid and 61% of the furfural and hydroxymethyl furfural.

**Separation:** The 26% insoluble solids present in the pre-hydrolysed slurry (containing 0.38% sulphuric acid) is treated is then separated on a filter press. A method of reducing the toxins remaining in the liquid portion is to wash with (recycled) water. After ion exchange for the removal of acetic acid, the liquid portion of the hydrolyzate is acidified to pH 2 by the addition of sulphuric acid. Lime is then added to raise the pH to 10 and heated to 50°C. The liquid is then

adjusted to the fermentation pH of 4.5 for 4 hours allowing gypsum crystals to form for separation by filtration.

**Simultaneous Saccharification and Co-Fermentation:** Detoxified and diluted hydrolysed solids is split to cellulase fermentations and SSCF fermenters. The hydrolysate feed stream is 22% soluble and insoluble solids. The portion of hydrolysate split off for *Z. mobilis* seed production is approximately 10%. The portion of hydrolysed solids split off for cellulase production is dependent on the cellulase yield on the xylose and cellulose present and the require loading of enzyme in the SSCF. For cellulase production pre-hydrolysed solids conditioned hydrolysate liquor, recycle water, corn steep liquor (to 1%) and nutrients  $((\text{NH}_4)_2\text{SO}_4, \text{KH}_2\text{PO}_4, \text{MgSO}_4 \cdot 7\text{H}_2\text{O}, \text{CaCl}_2 \cdot 2\text{H}_2\text{O}$  and Tween 80) and corn oil as an antifoam (0.1% v/v) are combined to give a final cellulose concentration of 4%. The batch is then run for 160 hours at 28°C to produce cellulase. For SSCF, detoxified hydrolysate slurry (22% total solids) is cooled to 30°C and added to the fermenter together with a 10%(v/v) seed inoculum. Addition of corn steep liquor to 0.25% and cellulase to give a final concentration of 15 FPU/g (cellulose) results in an initial cellulose concentration of 22%. The SSCF fermentation in which cellulose is converted to fermentable sugars by cellulase and the fermentable sugars converted to ethanol by *Z. mobilis* takes 7 days.

**Distillation:** A whole beer containing 5.1% ethanol by weight is fed to a distillation column where the ethanol concentration is reduced to 0.12% by weight, and generating vapour containing 37% by weight ethanol.

**Separation:** A 200 ml portion of the still bottom stream containing 7.5% suspended solids by weight and 2.5% soluble solids at 85°C was flocculated in a Triton mixer set at a speed of 1500 revs per minute and treated with a 65:35 blend of polymer 1 (polyDADMAC IV approx 1 dl/g) and polymer 2 (a cationic polymer active composition 20% acrylamide 80% cationic monomer dimethyl-aminoethyl methacrylate quaternized with methyl chloride having an IV of 4 dl/g preferably after shear as described in EP 0202780B) at a dose of 5 kg/Tds. The flocculated

11

stillage are allowed one minute of free drainage time. A free drainage of 80 ml in 5 seconds is obtained. A sample of the flocculated material was also transferred to a piston press. A press cycle of ten minutes is used with a maximum pressure of 100 psi. The 5 second filtrate volume was 101 ml and the cake solids was 31.4%.

Claims

1. A process of separating suspended solids from a fermentation liquor by subjecting the liquor to solids liquid separation stage, wherein the fermentation liquor is produced in a fermentation process for the production of a fermentation product, which liquor comprises water, lignin and BOD, wherein the solids liquid separation stage is assisted by a treatment system, characterised in that the treatment system comprises either,
  - (i) a cationic polymer having an intrinsic viscosity (IV) of at least 4 dl/g at a dose of above 2 kg/tonne based on dry weight of suspension, or
  - (ii) a cationic polymer having an intrinsic viscosity (IV) of at least 4 dl/g and,
  - (iii) an anionic polymer having, and/or
  - (iv) a cationic polymer of intrinsic viscosity of below 4 dl/g and a cationic charge density of at least 3 meq/g and/or
  - (v) inorganic coagulants and/or
  - (vi) charged microparticulate material.
2. A process according to claim 1 in which the fermentation liquor is subjected to a distillation stage wherein the fermentation product is recovered, wherein the liquor is removed from the distillation stage as a stillage stream and then subjected to the solids liquid separation stage.
3. A process according to claim 1 in which the fermentation liquor contains the fermentation product wherein the liquor is subjected to the solids liquid separation stage and then passed to a distillation stage wherein the fermentation product is recovered
4. A process according to any of claims 1 to 3 in which the treatment system comprises (i) a low IV cationic polymer of intrinsic viscosity of below 4 dl/g and a cationic charge density of at least 3 meq/g and (ii) a high IV cationic polymer of intrinsic viscosity of at least 4 dl/g.
5. A process according to any of claims 1 to 4 in which the low IV polymer is selected from the group consisting of polyamines, amine/epihalohydrin addition polymers, polymers of dicyandiamide with formaldehyde, polymers of diallyldimethyl ammonium chloride (DADMAC), cationic starch and cationic inulin.

6. A process according to any of claims 1 to 5 in which the inorganic coagulant is selected from alum and polyaluminium chloride (PAC).
7. A process according to claims 1 to 6 in which the coagulant is a charged microparticulate material,
8. A process according to any of claims 5 to 7 in which the high IV polymer is selected from water soluble or water swellable polymers, which polymer is a natural polymer or a synthetic polymer which has been formed from ethylenically unsaturated water-soluble monomer or monomer blend.
9. A process according to any of claims 5 to 8 in which the high IV polymer is either chitosan or a polymer of acrylamide with one or more water soluble cationic monomers selected from dialkylaminoalkyl (meth) acrylates, dialkylaminoalkyl (meth) acrylamides and acid addition salts or quaternary ammonium salts thereof.
10. A process according to any of claims 5 to 9 in which the coagulant and high IV polymer are added sequentially, preferably employing the coagulant first.
11. A process according to any of claims 5 to 10 in which the coagulant and high IV polymer are added simultaneously, preferably as a premix.
12. A process according to claim 11 in which the premix comprises (i) a low IV cationic polymer of intrinsic viscosity of below 4 dl/g and a cationic charge density of at least 3 meq/g and (ii) a high IV cationic polymer of intrinsic viscosity of at least 4 dl/g.
13. A process according to any of claims 1 to 12 in which the dose of coagulant is at least 50 grams per tonne (based on dry weight of fermentation liquor).
14. A process according to any of claims 5 to 13 in which the dose of high IV polymer is at least 50 grams per tonne (based on dry weight of fermentation liquor).
15. A process according to any of claims 1 to 14 in which the fermentation liquor is subjected to a mechanical dewatering stage during or subsequent to application of the treatment system.
16. A process according to claim 15 in which the mechanical dewatering step is selected from at least one of, a centrifuge, a screw press, a filter press, a belt filter press a horizontal belt filter or preferably a pressure filter.
17. A process according to any of claims 1 to 16 in which the treated liquor

from which suspended solids have been removed are recycled and used as wash water.

18. A process according to any of claims 1 to 17 in which the fermentation liquor comprises lignin and in which the separated solids are dewatered and then subjected to a drying stage to provide a dry solid material and in which the dry solid material is used as a solid fuel.

19. A process according to any of claims 1 to 18 in which the fermentation product is selected from the group consisting of ethanol, glycerol, acetone, n-butanol, butanediol, isopropanol, butyric acid, methane, citric acid, fumaric acid, lactic acid, propionic acid, succinic acid, itaconic acid, acetic acid, acetaldehyde and 3-hydroxypropionic acid.

**Abstract**

A process of separating suspended solids from a fermentation liquor by subjecting the liquor to solids liquid separation stage, wherein the fermentation liquor is produced in a fermentation process for the production of a fermentation product, which liquor comprises water, lignin and BOD, wherein the solids liquid separation stage is assisted by a treatment system, characterised in that the treatment system comprises either,

- (i) a cationic polymer having an intrinsic viscosity (IV) of at least 4 dl/g at a dose of above 2 kg/tonne based on dry weight of suspension, or
- (ii) a cationic polymer having an intrinsic viscosity (IV) of at least 4 dl/g and,
- (iii) an anionic polymer having, and/or
- (iv) a cationic polymer of intrinsic viscosity of below 4 dl/g and a cationic charge density of at least 3 meq/g and/or
- (v) inorganic coagulants and/or
- (vi) charged microparticulate material.
